How forecasts are made

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation and streamflow values are used in computerized statistical and simulation models to prepare runoff forecasts. These forecasts are coordinated between hydrologists in the Natural Resources Conservation Service and the National Weather Service. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

The United States Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, sex, religion, age, disability, political beliefs and marital or familial status. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at 202-720-2600 (voice and TDD).

To file a complaint, write the Secretary of Agriculture, U.S. Department of Agriculture, Washington, D.C., 20250, or call 1-800-245-6340 (voice) or (202) 720-1127 (TDD). USDA is an equal employment opportunity employer.

• Provides an overview of Arizona's crop, livestock, range and pasture conditions as reported by local staffs of the USDA's Agricultural Statistic Service and University of Arizona.

SUMMARY

Snow measurements confirm that Arizona's snowpack levels have increased since Jan. 1. Statewide, the snowpack is 63% of the 30-yr. average, compared with 41% on Jan. 1. While overall snowpack numbers have increased, it is important to note that all basins tracked in this report lag behind the 30-yr. average for Feb. 1. As a result, water managers can expect short water supplies this season.

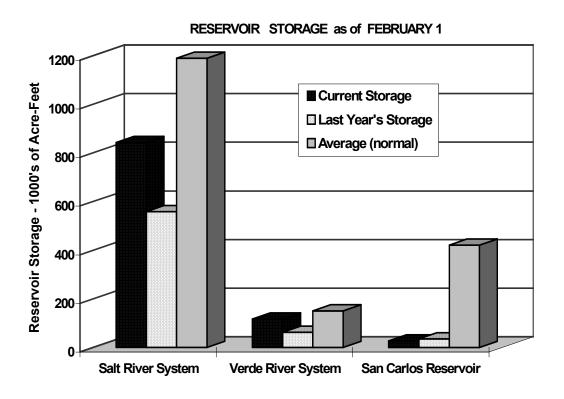

SNOWPACK

Key Watersheds	Percent (%) of 30-Yr. Average Snowpack Levels as of February 1
Salt River Basin	62%
Verde River Basin	50%
Little Colorado River Basin	55%
San Francisco-Upper Gila River Basin	60%
Other Points of Interest	
Chuska Mountains	73%
Central Mogollon Rim	57%
Grand Canyon	73%
San Francisco Peaks	69%
Statewide Snowpack	63%

PRECIPITATION

Mountain data, from 15 NRCS SNOTEL sites, show that precipitation catch for January is below the 30-yr. average at all sites. For more information, please refer to the precipitation bar graphs found in this report.

RESERVOIR

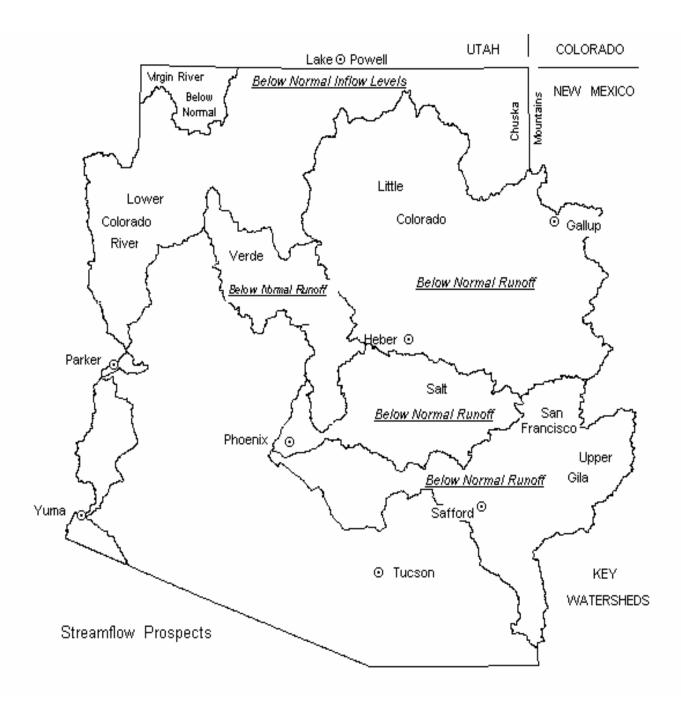

Key storage volumes displayed in thousands of acre-feet(1000x):

	CURRENT	LAST YEAR	30-YEAR
RESERVOIR	STORAGE	STORAGE	AVERAGE
Salt River System	842.5	558.8	1189.3
Verde River System	117.0	62.7	150.8
San Carlos Reservoir	27.2	36.1	421.8
Lyman Lake	2.1	2.2	14.7
Show Low Lake	3.2	2.0	2.9
Lake Pleasant	552.1	452.9	
Lake Havasu	510.6	537.1	551.8
Lake Mohave	1623.4	1705.3	1672.3
Lake Mead	15434.0	16854.0	21992.0
Lake Powell	10984.0	13269.0	18463.0

STREAMFLOW

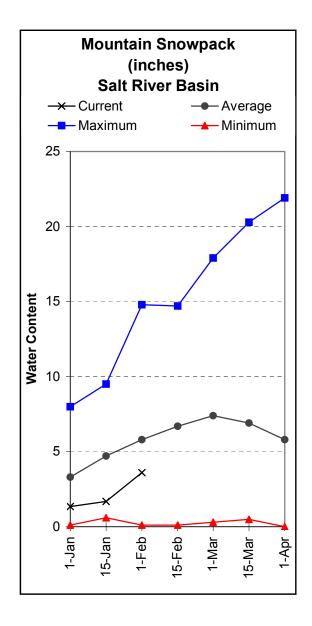

The long-term forecast (Feb-May) calls for well below normal runoff this season due to poor snowpack levels in key watersheds.

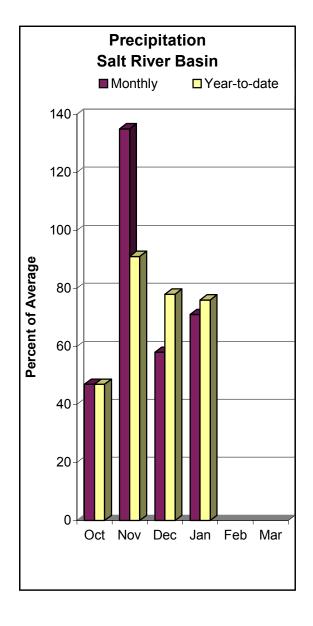

SALT RIVER BASIN as of February 1, 2004

Well below median streamflow levels are forecast for the basin. In the Salt River, near Roosevelt, the forecast calls for 54 % of median streamflow levels through MAY, while in Tonto Creek, the forecast calls for 30 % of median streamflow levels through MAY.

Snow survey measurements show the Salt snowpack to be 62 % of the 30-year average, while combined reservoir storage on the Salt River system is reported at 842,466 acre-feet.

VERDE RIVER BASIN as of February 1, 2004

Well below median streamflow levels are forecast for the basin. In the Verde River, at Horseshoe Dam, the forecast calls for 50 % of median streamflow levels through MAY.

Snow survey measurements show the Verde snowpack to be 50 % of the 30-year average, while combined reservoir storage on the Verde River system is reported to be 117,047 acre-feet.

SAN FRANCISCO-UPPER GILA RIVER BASIN as of February 1, 2004

Well below median streamflow levels are forecast for the basin. In the San Francisco River, at Clifton, the forecast calls for 48 % of median streamflow levels through MAY, while in the Gila River, near Solomon, the forecast calls for 40 % of median streamflow levels through MAY. At San Carlos Reservoir, inflow into the lake is forecast at 36 % of median through MAY.

At San Carlos, reservoir storage stands at 27,264 acre-feet, while snow survey measurements show snowpack levels to be 60 % of the 30-year average.

LITTLE COLORADO RIVER BASIN as of February 1, 2004

Well below median streamflow levels are forecast for the basin. In the Little Colorado River, at Lyman Lake, the forecast calls for 39 % of median streamflow levels through JUNE, while at Woodruff, the forecast calls for 39 % of median streamflow levels through MAY.

Additionally, snowpack levels along the southern headwaters of the Little Colorado River, and along the central Mogollon Rim, were measured at 55 % and 57 % of the 30-year average, respectively.
